

Cause of unplanned early reoperation, by index surgical approach

No difference detected in the overall rate — laparoscopic 24/255 (9.4%) vs. open-related 12/195 (6.2%), $p=0.22$.

The composition differed: duodenal obstruction after laparoscopy, necrosis and perforation after open surgery.

Bars are cause-specific rates with the full approach group as the denominator; numerals are event counts. 95% CIs in Table 2.

The duodenal-obstruction comparison is confounded by age and is shown stratified in Figure 2.
